

## MATH 437 Homework 5 (20 points)

1. Consider  $Ax = b$  with

$$A = \begin{bmatrix} 7 & -1 & 1 & 1 \\ 3 & 9 & 9 & 1 \\ 3 & 3 & 15 & 1 \\ 3 & 3 & 5 & 14 \end{bmatrix}, \quad b = \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \end{bmatrix}.$$

- (a) (1 point) Solve this equation using the Jacobi iterative method with tolerance  $10^{-5}$ . Report the residuals and the number of iterations.
- (b) (1 point) Solve this equation using the Gauß–Seidel iterative method with tolerance  $10^{-5}$ . Report the residuals and the number of iterations.
- (c) (1 point) Solve this equation using the SOR iterative method with tolerance  $10^{-5}$  and  $\omega = 1.0911$ . Report the residuals and the number of iterations.
- (d) (1 point) Compare the spectral radius of the iteration matrix for these methods.

*Hint.* We recall that all of the iterative methods are of the form

$$Ex^{n+1} + Bx^n = b,$$

For Jacobi,  $E := D$ , the diagonal of  $A$ . For Gauß–Seidel,  $E := D + L$ , where  $L$  is the strictly lower-triangular part of  $A$ . For SOR,  $E := \omega^{-1}D + L$ . In all 3 cases,  $B := A - E$ .

The iteration matrix is

$$T := E^{-1}B.$$

The spectral radius of  $T$  is then

$$\rho(T) := \max\{|\lambda| : \lambda \text{ eigenvalue of } T\}.$$

Thus, we find the eigenvalues of  $T$  numerically and take the largest in magnitude. For the implementation, see `problem_1.py`. □

2. (4 points) Let  $n > 0$ , and let  $A$  be the  $n \times n$  tridiagonal matrix with entries  $-2$  on the main diagonal and  $1$  on the off-diagonals. Let  $b$  be the  $n$ -dimensional vector with first and last entry  $1$  and all other entries  $0$ . Consider the linear equation

$$Ax = b.$$

For  $n = 10$ ,  $n = 20$ , and  $n = 40$ , solve this system using the Gauß–Seidel method with tolerance  $10^{-5}$  and report the number of iterations along with the residual at the last iteration. How does increasing  $n$  affect the number of iterations?

*Hint.* See `problem_2.py`.

□

3. (3 points) Find the condition number of

$$A = \begin{bmatrix} 0.04 & 0.01 & -0.01 \\ 0.2 & 0.5 & -0.2 \\ 1 & 2 & 4 \end{bmatrix}$$

with respect to the  $\|\cdot\|_\infty$  norm to at least 6 digits of accuracy.

*Hint.* The condition number of a matrix  $A$  with respect to a matrix norm  $\|\cdot\|$  is

$$K(A) := \|A\| \|A^{-1}\|.$$

For the  $\|\cdot\|_\infty$  matrix norm,

$$\|A\|_\infty = \max_i \sum_j |A_{ij}|.$$

□

4. (a) (2 points) Compute the  $\ell_2$  and  $\ell_\infty$  norms of  $x := (3, -4, 0, 2)$ .  
(b) (1 point) Compute the  $\ell_\infty$  norm of the matrix

$$A := \begin{bmatrix} 1 & -1 & 1 \\ 1 & 3 & -1 \\ 3 & 0 & 1 \end{bmatrix}$$

*Hint.*

(a)

$$\|x\|_2 = \sqrt{\sum_i x_i^2},$$

$$\|x\|_\infty = \max_i |x_i|.$$

(b)

$$\|A\|_\infty = \max_i \sum_j |A_{ij}|.$$

□

5. (3 points) If the matrix

$$A = \begin{bmatrix} 1 & 2 & -1 \\ 0 & 1 & 2 \\ -1 & 4 & 3 \end{bmatrix}$$

is nonsingular, compute its inverse using Gauß–Jordan elimination.

*Hint.* Just proceed with Gauß–Jordan elimination process on the augmented matrix

$$[A \quad I],$$

where  $I$  is the identity matrix. Here's an example on a  $2 \times 2$  matrix.

$$\begin{aligned} \begin{bmatrix} 1 & 2 & 1 & 0 \\ 4 & 3 & 0 & 1 \end{bmatrix} &\xrightarrow{R_2 - 4R_1 \rightarrow R_2} \begin{bmatrix} 1 & 2 & 1 & 0 \\ 0 & -5 & -4 & 1 \end{bmatrix} \\ &\xrightarrow{R_2 / -5 \rightarrow R_2} \begin{bmatrix} 1 & 2 & 1 & 0 \\ 0 & 1 & 4/5 & -1/5 \end{bmatrix} \\ &\xrightarrow{R_1 - 2R_2 \rightarrow R_1} \begin{bmatrix} 1 & 0 & -3/5 & 2/5 \\ 0 & 1 & 4/5 & -1/5 \end{bmatrix}, \end{aligned}$$

so

$$\begin{bmatrix} 1 & 2 \\ 4 & 3 \end{bmatrix}^{-1} = \frac{1}{5} \begin{bmatrix} -3 & 2 \\ 4 & -1 \end{bmatrix}.$$

□

6. (a) (1 points) Compute the determinant of the matrix

$$A = \begin{bmatrix} 2 & -1 & 1 \\ 3 & 3 & 9 \\ 3 & 3 & 5 \end{bmatrix}$$

- (b) (2 points) Factor the above matrix into an  $LU$  decomposition with  $L_{ii} = 1$  using Gaussian elimination.

*Hint.*

- (a) For a general  $3 \times 3$  matrix

$$A = \begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix},$$

the determinant is computed by expanding along any row or column. For example, expanding along the first row,

$$\det(A) = a_{11} \det \begin{bmatrix} a_{22} & a_{23} \\ a_{32} & a_{33} \end{bmatrix} - a_{12} \det \begin{bmatrix} a_{21} & a_{23} \\ a_{31} & a_{33} \end{bmatrix} + a_{13} \det \begin{bmatrix} a_{21} & a_{22} \\ a_{31} & a_{32} \end{bmatrix}.$$

- (b) Let  $R_{c,i,j}$  denote the transformation that adds  $c$  times row  $i$  of a matrix to row  $j$ , where  $i \neq j$ . In matrix-form,

$$R_{c,i,j} = I + cE_{j,i},$$

where  $I$  is the identity matrix and  $E_{j,i}$  is the square matrix with all entries 0 except a 1 in the  $(j, i)$  entry. For example, in a  $3 \times 3$  matrix,

$$R_{2,1,2} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} + 2 \begin{bmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ 2 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}.$$

Now, we do Gaussian elimination on  $A$  to reduce it to an upper-triangular matrix  $U$ . The reductions we perform will be of the form  $R_{c,i,j}$ . Each reduction corresponds by multiplying on the left by such an  $R_{c,i,j}$ .

We use row 1 to eliminate the  $(2, 1)$  entry and the  $(3, 1)$  entry, and then we use row 2 to eliminate the  $(3, 2)$  entry. Thus, we arrive at an equation of the form

$$R_{c_3,2,3}R_{c_2,1,3}R_{c_1,1,2}A = U,$$

where  $U$  is the upper-triangular matrix we seek. Since  $A = LU$ , we conclude that

$$\begin{aligned} L &= (R_{c_3,2,3}R_{c_2,1,3}R_{c_1,1,2})^{-1} \\ &= (R_{c_1,1,2})^{-1}(R_{c_2,1,3})^{-1}(R_{c_3,2,3})^{-1}. \end{aligned}$$

Now, for  $i \neq j$ ,

$$(R_{c,i,j})^{-1} = R_{-c,i,j},$$

which corresponds to subtracting  $c$  times row  $i$  from row  $j$ . Therefore,

$$L = R_{-c_1,1,2}R_{-c_2,1,3}R_{-c_3,2,3}.$$

Reading from right to left, this says subtract  $c_3$  of row 2 from row 3, then subtract  $c_2$  of row 1 from row 3, and then subtract  $c_1$  of row 1 from row 2. Applying these steps to the identity matrix, we end with

$$L = \begin{bmatrix} 1 & 0 & 0 \\ -c_1 & 1 & 0 \\ -c_2 & -c_3 & 1 \end{bmatrix},$$

which, with  $U$  above, finishes the problem. □
